Investigation of the A=7 systems within the No-Core Shell Model with Continuum

Friday, 31 May 2019 16:30 (15 minutes)

One of the recently developed approaches capable of describing both bound and scattering states in light nuclei simultaneously is the No-Core Shell Model with Continuum (NCSMC).

This technique represents a state-of-the-art *ab initio* approach and combines the No-Core Shell Model (NCSM) description of short-range correlations with the clustering

and scattering properties of the Resonating Group Method. Recent NCSMC calculations of ⁷Be and ⁷Li will be presented. The properties of these nuclei were investigated

by analyzing the continuum of all the binary mass partitions involved in the creation of these systems, using chiral interactions as the only input.

Our calculations reproduce all the experimentally known states in the correct order and predict new possible resonances with negative and positive parity. A positive-parity S wave resonance is found analyzing the continuum of p + ⁶He at a very low energy above the threshold, which produces a very pronounced peak in the astrophysical S factor of

the 6 He(p, γ) 7 Li radiative capture. Possible implications for astrophysics have still to be investigated.
